

VARIABLE EXPOSURE IMAGES FUSION USING DISCRETE COSINE TRANSFORMS

Vivek Ramakrishnan, D. J. Pete

Abstract - Fusing images with different exposure settings are of prime importance in the field of computational photography. Both transform domain approach and filtering based approaches are possible for combining multiple exposure images, to obtain the well-exposed image. A Discrete Cosine Transform (DCT-based) approach for fusing multiple exposure images has been proposed in this work. The input image stack is processed in the transform domain by an averaging operation and the inverse transform is performed on the averaged image obtained to generate the fusion of multiple exposure image. The experimental observation leads us to the conjecture that the obtained DCT coefficients are indicators of parameters to measure well-exposedness, contrast and saturation as specified in the traditional exposure fusion based approach and the averaging performed indicates equal weights assigned to the DCT coefficients in this non-parametric and non pyramidal approach to fuse the multiple exposure image stack

Keywords – Discrete, Exposure, Cosine, Fusion, Coefficients, Transform, Contrast, Saturation, Weights

I. INTRODUCTION

The classical approach [13] to fuse multiple-exposure image set involves Laplacian pyramid and finding the characteristic parameters like Saturation, Contrast and Well-exposedness and fusing them using the Gaussian weighting scheme. Later approaches like fusing multiple exposure images with like the ones listed in [2], and transform domain approaches started to evolve. Pixel based representation of images are possible on paper and traditional display devices. For colour image displays we assign three channels R,G and B channel and assign 8 bit per pixel for each channel. So for every colour channel 256 possible values are formed. Figure 1 depicts the variable exposure stack of the Office images. Figure 2 depicts the generated HDR image. Figure 3 shows the tone-mapped LDR image. Various HDR formats such as the ones stated below are listed in [39]

1. OPENEXR FORMAT (or EXtended Range format or '.exr' format.).
2. Other encoding sviz. sRGB48, ScRGB-nl, ScYCC-nl
3. TIFF float and the LOGLUV format.
4. HDR format (.hdr, .pic format), originally known as the Radiance picture format and Lossy HDR encodings.

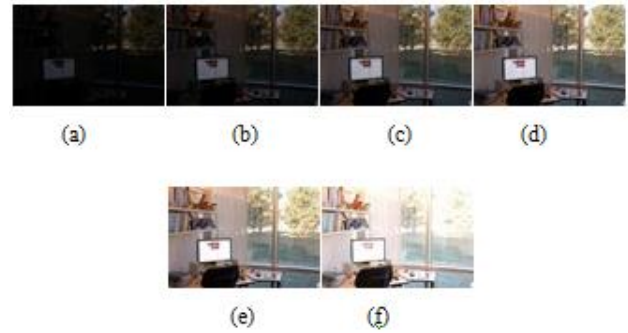

Fig.1: Set of Six Multiple Exposure Office Images

Fig.2: HDR image of Office

Fig.3: Tone-mapped Image of HDR image of

The variable exposure image stack is transformed to the DCT domain, the averaging operation is performed on the transform domain coefficients and the inverse transform is performed on the smoothed coefficients to obtain the fused image. The block variance is allowed to have a statistical distribution, and the DCT coefficients follow a Laplacian nature [40] this then implies that we exploit the Laplacian nature of the coefficients which follows similar nature of the Laplacian distribution or Laplacian pyramidal decomposition in the spatial domain on which we perform the traditional exposure fusion.

II. CHALLENGES INVOLVED IN HDR IMAGE CAPTURE

We are not able to measure the radiance distribution of the scene using the traditional cameras, its not possible to capture the full spectral content and dynamic range. There are inherent limitations in most digital image sensors so

as to not make it possible to capture the entire dynamic range of a scene in a single exposure setting. A standard camera records multiple exposures with the right software. Selection of the right pixel to be combined to obtain the fused image is another challenging task.

Inherent assumptions include

1. Capturing device is perfectly linear
2. Each pixel in every exposure needs to be brought into the same irradiance domain
3. Corresponding pixels are averaged across the exposures.
4. Over and under exposed pixels must be excluded

The further section discusses in detail the classical HDR imaging technique, by Debevec et. al. [2]. Then we describe the classical exposure fusion technique in the spatial domain involving pyramidal decomposition and Gaussian weighting by Mertens et. al. [1] further ahead evolving to the transform domain approaches and to the current work based on a non-pyramidal and uniform weighting approach based on DCT.

III. RELATED WORK

A camera of limited dynamic range is able to capture an Output referred image rather than a Scene referred image which is possible through HDR. This approach works basically in the spatial domain. Multiple exposure image set is obtained and each image gets treated by the estimated inverse camera response function (CRF). Weighted pixel blending is carried out to obtain the exposure fused image [1]. Sometimes a Multi Resolution Analysis (MRA) based blending is carried out which being a pyramidal decomposition approach gives rise to visible seams and blur. There also arises a need to go for higher order pyramidal decomposition.

Debevec et. al. [8] developed a technique in which different exposure images are combined into a single radiance map such that the pixel values are in proportion to the radiance values. Bogoni and Hansen [24] stated an in which the Luma and the Chroma components were decomposed into Laplacian pyramid and Gaussian pyramid respectively. A fusion based on Illumination estimation was suggested by [25], Vonikakis et. al. The problem of motion blur in longer exposure images was addressed by Tico et. al. [26]. In the method developed by Jinho and Okuda [27] they designed weighting functions that not dependant on exposure areas. Shen [28] used Generalized random walks to arrive at an optimal solution. Li and Kang [29] suggested a weighted sum fusion approach. Independent Component Analysis (ICA) was used by Mitianoudis and Stathaki [30] to propose

their fusion scheme. Fusion involving weighted averaging of the input image stack was proposed in ([5], [6],[7]). Fusion approaches based on the irradiance values, and not the intensity values of the pixels was developed in ([8], [9]). Transform based approach are discussed in ([38], [4]). Goshtasby developed a block based fusion approach [10]. Compositing without Matte was developed in [12] and the classical exposure fusion approach in [13] are two other important techniques of compositing. Bi lateral filter based method is suggested in [1]. A Bayesian approach for Matte generation is suggested in [11]. Approaches related to Markov random field [14], boundary location information [15], Poisson Solver based [16] and an optimization approach in [17] are other fully developed techniques. Making use of the fore(back)ground statistics an approach was developed in [18], using motion cues in [19] and through defocus cue in [20]. A generalistic α blending approach is stated in [21].

IV. SOME POPULAR HDR IMAGING TECHNIQUES USED FOR COMPARISON IN THIS WORK

We now give a brief account of some state of the art HDR imaging techniques which are popular and can be used for comparison with this technique. Ashikmin et. al. [31] developed a technique which approach which maps the HDR image input to the luminance values possible to displayed by the display device, Banterlee et. al. [32] presented a luminance zone based approach where every zone is processed by a Tone Mapping Operator (TMO) compatible for each zone. Raman et. al. [1] developed a bilateral filter based compositing. Bruce et. al. [33] developed a fusion approach based on relative entropy. Lischinski et. al. A method based on interactive local adjustment of tonal values was proposed by [34]. Tan et. al. [35] provides a logarithmic tone mapping algorithm. Mertens et. al. [13] present a parametric classical multiple exposure fusion approach. Reinhard et. al. [36] present a traditional tone mapping methodology. In addition we have transform domain approaches [4] and edge preserving Savitsky Golay filtering based approach [37].

^aGaussian units are the same as cgs emu for magnetostatics; Mx = maxwell, G = gauss, Oe = oersted; Wb = weber, V = volt, s = second, T = tesla, m = meter, A = ampere, J = joule, kg = kilogram, H = henry.

V. THE DISCRETE COSINE TRANSFORM

The Discrete Cosine Transform used mainly in JPEG compression is a block transform. The basic formulation of the DCT was done by Ahmed et al. [46]. DCT exhibits unitary property and is similar to the Karhunen-Loève Transform (KLT). It has got good energy compaction efficiency and rate distortion function.. In the KLT [47] we observe decorrelated transform coefficients and the signal energy is compacted in the first fewest sub-bands. The $N \times N$ cosine transform matrix $V = v(k, n)$, also known as the Discrete Cosine Transform (DCT) which is defined as follows for $k = 0$ and $0 \leq n \leq (N - 1)$.

$$v(k, n) = \frac{1}{\sqrt{N}} \quad (8)$$

and for $0 \leq k \leq (N - 1)$, $0 \leq n \leq (N - 1)$

$$v(k, n) = \frac{\sqrt{2}}{\sqrt{N}} * \cos \frac{\pi(2n+1)k}{2N} \quad (9)$$

The properties of DCT are

1. DCT is not the real part of the unitary Discrete Fourier Transform (DFT)
2. DCT is real orthogonal
3. DCT is a fast transform.
4. Excellent energy compaction efficiency is seen in the DCT for highly correlated data.
5. The basis vectors of DCT are eigenvectors of the symmetric tridiagonal matrix.
6. DCT is very close to the KLT.

VI. REGARDING DISTRIBUTION OF 2-D BLOCK DCT COEFFICIENTS

Pratt (1978) [41] carried out the earlier work on DCT Coefficients, it was conjectured that the DC coefficients are Rayleigh distributed assuming no level shift and the AC coefficients are Gaussian distributed according to the central limit theorem considering each pixel to be statistically independent from another. Tescher (1979) [42] and Mu-rakami, Hatori and Yamamoto (1982) [43] indicated that the AC coefficients are Laplacian distributed, and the DC coefficients are Gaussian distributed. Reininger and Gibson [44] also asserted that DC coefficient follow a Gaussian PDF, and AC coefficients follow a Laplacian PDF. Reininger and Gibson performed the Kolmogorov-Smirnov (KS) test [45] on a 256x256 8-bit PCM grayscale images over multiple modes, and determined the best fit for the different PMFs. Observing the results of the (KS) tests

[44] it is concluded that the AC block DCT coefficients follow a Laplacian distribution.

VII. MOTIVATION

The drawbacks of fusion in the spatial domain include

1. Brightness changes are vast around the edges.
2. Low pass filtered version is subtracted from the original to get the Laplacian pyramid based decomposition.
3. Pixels with higher frequency that is higher rate of change of illumination are retained.
4. We get reduced number pixels by sub-sampling the edges.
5. Sub-sampling gives disadvantage of approximating the non-edge pixels with the highly varying brightness edge pixels.
6. The weight maps also depict severe variations.
7. There is degradation in the contrast and there are low frequency brightness change in the pixels which are not edge pixels.

VIII. OUR METHOD

The steps involved in our algorithm are as follows

1. Perform the DCT transform of all the images in the image stack.
2. The DCT Coefficients of all these images are averaged out to obtain the resultant final image in the transform domain.
3. The inverse DCT transform of the resultant image in the transform domain is performed to obtain the fused result.

Thus we can note that all the pixels have equal prominence so equal weights are assigned to all the pixels which are captured in the transform domain. The transform coefficients are empowered enough to give prominence in their luma value and chroma values according to the exposure.

IX. RESULTS AND DISCUSSION

The DCT-based exposure fusion outputs are compared with the techniques described in ([1],[4],[13],[31],[32],[33],[34],[35],[36] and [37]). The PSNR and the SSIM scores are improved. There is a decrease in error i.e. the IMMSE scores. High Q Scores are obtained using the VDP metric [23].

For the following set of images obtained as results, shown in figures 5 and 7 kindly refer to the table 1 shown below for knowing which of the sub-figure was generated using what approach.

X. CONCLUSION

Thus fusion of multiple exposure images using the DCT-based transform domain approach has been developed and the results stated. The results favor the use of DCT- based

multi-exposure image fusion for the High Dynamic Range Imaging problem.

ACKNOWLEDGEMENTS

Tom Mertens, Frank Van Reeth and Jan Kautz are thanked for the set of multiple exposure images in Fig. (4). The CAVE Computer Vision Laboratory, Columbia University is thanked for the multiple exposure images in the Figures, Fig.(6).
